April 23, 2013

## Abstract

We study two-player common-value all-pay auctions (contests) with asymmetric information under the assumption that one of the players has an information advantage over his opponent. We characterize the unique equilibrium in these contests, and examine the role of information in determining the players' expected efforts, probabilities of winning, and expected payoffs. In particular, we show that the players always have the same probability of winning the contest, and that their expected efforts are the same, but their expected payoffs are different. It is also shown that budget constraints may have an unanticipated effect on the players' expected payoffs, i.e., a player's information advantage may turn into a payoff disadvantage.

**Keywords:** Common-value all-pay auctions, asymmetric (differential) information, information advantage, budget constraints.

**JEL Classification:** C72, D44, D82.

# 1 Introduction

All-pay auctions are used in diverse areas of economics, such as lobbying in organizations, R&D races, political contests, promotions in labor markets, trade wars, and biological wars of attrition. In the all-pay auction each player submits a bid (effort) and the player who submits the highest bid wins the contest, but, independently of success, all players bear the cost of their bids. All-pay auctions have been studied both under a complete information framework where each player's type (the value of winning the contest or ability) is common knowledge (see, e.g., Hillman and Samet (1987), Hillman and Riley (1989), Baye et al. (1993, 1996), Che and Gale (1998), and Siegel (2009)), and under an incomplete information framework where each player's type is private information and only the distribution from which the players' types is drawn is common knowledge (see, for example, Amann and Leininger (1996), Moldovanu and Sela (2001, 2006), and Moldovanu et al. (2010)). In most of the literature on all-pay auctions with incomplete information it is assumed that the players' types are independent. However, in several competitive environments the players' types may not be independent (see Milgrom and Weber 1982).<sup>1</sup> Krishna and Morgan (1997) analyzed the equilibrium strategies of the all-pay auction with interdependent types in the Harsanyi-type formulation of Bayesian games. They assumed that the players' types are affiliated and symmetrically distributed. A generalization of their work to a model where players' types are asymmetrically distributed is usually not tractable.

We study the value of information in a contest with ex-ante asymmetrically informed players by considering a two-player common-value all-pay auction with asymmetric information, where the value of winning is the same for all players in the same state of nature, but the information about which state of nature was realized is different. This model captures situations in which winning a contest would be of similar benefit to each contestant, but the precise value of winning, which depends on several random parameters, may be unknown. In our framework, the information a player has about the value of winning is described by a partition of the space of states of nature, which is assumed to be finite. This partition representation is equivalent to the more common Harsanyi-type formulation of Bayesian games (see Jackson (1993) and Vohra (1999)) but it is more suitable for expressing the information advantage some players may have over others,

---

<sup>1</sup>Examples of auctions with interdependent values include treasury bill auctions, spectrum auctions, and oil and gas leases.

which will figure prominently in our model.

In our (two-player) model of asymmetric information, we assume that information sets of each player are connected with respect to the value of winning the contest (see Einy et al. (2001, 2002) and Forges and Orzach (2011)). This means that if a player's information partition does not enable him to distinguish between two possible values of winning, then he also cannot distinguish between all intermediate values. Connectness seems plausible in environments where the information of a player allows him to put upper and lower bounds on the actual value of winning, without ruling out any outcome within these bounds. We additionally assume that one player has an information advantage over the other, which means that his information partition is finer than that of his opponent. It can be shown that in equilibrium analysis we can assume without loss of generality that one player is completely informed about the state of nature, while the other player is completely uninformed.

We establish the uniqueness of equilibrium in mixed strategies in this class of contests, and provide its complete characterization. In equilibrium, the expected payoff of the uninformed player is zero, while the expected payoff of the informed player is positive. Our results also show that although the players have asymmetric strategies that yield different expected payoffs, the expected efforts of both players are the same. Moreover, the probability of each player to win the contest in equilibrium is the same. Hence, we find that asymmetry of information between the players does not result in different expected efforts or different chances to win the contest, but it does affect the allocation of payoffs between the players.

We then examine how the relation between players' information sets affect their expected total effort. We find that maximizing the total effort calls for narrowing the information gap between the players. Specifically, if there are three players ( $a, b$  and  $c$ ) where  $a$  has an information advantage over  $b$  who has an information advantage over  $c$ , then the expected total effort in the contest between  $a$  and  $c$  is necessarily lower than in the contest between  $b$  and  $c$ . In other words, when the players' information are similar to each other their total effort is larger.

Finally, we assume that players face budget constraints, which implies that there are caps on the bids that the players are able to place. A budget constraint changes the players' equilibrium behavior compared to the same contests without budget constraints. This was shown, among others, by Che and Gale (1998)

and Gaviious, Moldovanu and Sela (2003) in the standard all-pay auction under complete and incomplete information.<sup>2</sup> This observation is also valid in common-value all-pay auctions where the budget constraint may drastically change the relation between the players' expected payoffs. Furthermore, we show that the budget constraint may imply the unusual result according to which the player with the information advantage will have a lower expected payoff than his opponent. In other words, an information advantage may turn into a payoff disadvantage.

Several researchers used the same framework as ours to analyze common-value second-price auctions (see Einy et al. (2001, 2002), Forges and Orzach (2011), and Abraham et al. (2012)) and common-value first-price auctions (see Malueg and Orzach (2009, 2012)) but not to analyze asymmetric all-pay auctions. Without budget constraints, in the common-value all-pay auctions, as well as in the common-value first-price and second-price auctions, the player with an information advantage has a higher expected payoff than his opponent. However, in common-value all-pay auctions the players' bids (efforts) as well as their chances of winning are the same despite the asymmetry of information.

The models most related to our common-value all-pay auctions are Warneryd (2003, 2012, 2013) and Siegel (2013). Warneryd (2003, 2012) studied Tullock contests with asymmetric information where the common value has a continuous distribution over a bounded interval (which implies a continuum of possible states of nature).<sup>3</sup> He analyzed the equilibrium when some players know the state of nature and others know only its prior distribution. Under the same assumption of extreme asymmetry of information, Warneryd (2013) also studied common-value all-pay auctions. He showed that the information does not affect the players' probability of winning the contest which is also the case in our model.<sup>4</sup> Siegel (2013) studied asymmetric two-player all-pay auctions with interdependent valuations and showed the existence of a unique equilibrium. He provided an algorithm to calculate the equilibrium, but did not derive a closed-form equilibrium which is necessary for our analysis of the role of information in determining the players' expected efforts, probabilities of winning, and expected payoffs.

---

<sup>2</sup>Che and Gale (1998) and Gaviious, Moldovanu and Sela (2003) deal with all-pay auctions with bid caps (budget constraints that the contest designer imposes on the contestants).

<sup>3</sup>Warneryd (2012) is an extension of Warneryd (2003) to any number of players.

<sup>4</sup>The equilibria in the two frameworks are of different types, however: the informed player in Warneryd (2013) plays a pure strategy, while the corresponding player in our model strictly mixes his best responses in all states of nature.

Although we analyze two-player (common-value all-pay) auctions, our results can be generalized to any number of players as long as the players' information partitions can be ranked, namely, in all pairwise comparisons one player will have an information advantage over the other. In such a case, as well as in the complete information all-pay auction (see Baye et al. (1996)), there will be an equilibrium in which only the two most informed players participate, and the rest stay out of the contest (or, alternatively, place bids of zero).

The paper is organized as follows. In Section 2 we present the model. In Section 3 we give a numerical example that demonstrates how to find the equilibrium in our model. Section 4 is divided into three subsections: In Section 4.1 we characterize the equilibrium and prove its uniqueness. In Section 4.2 we analyze the players' expected effort, their probabilities of winning, and their expected payoffs. In Section 4.3 we examine the effect of information on the players' total effort. In section 5 we study the model with budget-constrained players. Section 6 concludes. The proof of Proposition 1 is provided in the appendix.

## 2 The model

Consider the set  $\mathcal{N} = \{1, 2, \dots, N\}$  of  $N \geq 2$  players who compete in an all-pay auction where the player with the highest effort (output) wins the contest, but all the players bear the cost of their effort. The uncertainty in our model is described by a finite set  $\Omega$  of states of nature, and a probability distribution  $p$  over  $\Omega$  which can be interpreted as the common prior belief about the realized state of nature (w.l.o.g.  $p(\omega) > 0$  for every  $\omega \in \Omega$ ). A function  $v : \Omega \rightarrow \mathbb{R}_+$  represents the common value of winning the contest, i.e., if  $\omega \in \Omega$  is realized then the value of winning is  $v(\omega)$  for every player.

The private information of each player  $n \in \mathcal{N}$  is described by a partition  $\Pi_n$  of  $\Omega$ . We assume that each  $\Pi_n$  is *connected* with respect to the common value function  $v$ , i.e., for every element  $\pi_n \in \Pi_n$ , if  $\omega_1, \omega_2 \in \pi_n$  and  $\omega \in \Omega$  satisfy  $v(\omega_1) \leq v(\omega) \leq v(\omega_2)$ , then  $\omega \in \pi_n$ .<sup>5</sup>

A common-value all-pay auction starts when nature chooses a state  $\omega$  from  $\Omega$  according to the distribution

---

<sup>5</sup>It is worth noting that our analysis remains valid if  $\Omega$  is an infinite set of states of nature provided the partitions are finite. To see this simply replace  $\Omega$  with a finite  $\Omega'$ , which is the coarsest partition of  $\Omega$  that refines all  $\{\Pi_n\}_{n \in \mathcal{N}}$ , and, for each  $\pi \in \Omega'$ , let the value of winning at  $\pi$ ,  $v(\pi)$ , be equal to the conditional expectation  $E(v(\cdot) | \pi)$ .

$p$ . Each player  $n \in \mathcal{N}$  is informed of the element  $\pi_n(\omega)$  of  $\Pi_n$  which contains  $\omega$ . Thus,  $\pi_n(\omega)$  constitutes the information set of player  $n$  at  $\omega$ , and then he chooses an effort  $x_n \in \mathbb{R}_+$ . The players will typically have different information partitions, and thus are ex-ante asymmetric.

The utility (payoff) of player  $n \in \mathcal{N}$  is given by the function  $u_n : \Omega \times \mathbb{R}_+^N \rightarrow \mathbb{R}$  as follows:

$$u_n(\omega, x) = \begin{cases} \frac{1}{m(x)}v(\omega) - x_n, & \text{if } x_n = \max\{x_k\}_{k \in \mathcal{N}}, \\ -x_n, & \text{if } x_n < \max\{x_k\}_{k \in \mathcal{N}}, \end{cases}$$

where  $m(x)$  denotes the number of players who exert the highest effort, namely,  $m(x) = |\{n \in \mathcal{N} : x_n = \max\{x_k\}_{k \in \mathcal{N}}\}|$ .

A common-value all-pay auction with differential information is fully described by and identified with the collection  $G = (N, (\Omega, p), \{u_n\}_{n \in \mathcal{N}}, \{\Pi_n\}_{n \in \mathcal{N}})$ .

In all-pay auctions, there is usually no equilibrium in pure strategies. Thus our attention will be given to mixed strategy equilibria. A mixed strategy of player  $n \in \mathcal{N}$  is a function  $F_n : \Omega \times \mathbb{R}_+ \rightarrow [0, 1]$ , such that for every  $\omega \in \Omega$ ,  $F_n(\cdot, \cdot)$  is a cumulative distribution function (c.d.f.) on  $\mathbb{R}_+$ , and for all  $x \in \mathbb{R}_+$ ,  $F_n(\cdot, x)$  is a  $\Pi_n$ -measurable function (that is,  $F_n(\cdot, x)$  is constant on every element of  $\Pi_n$ ). If player  $n$  plays a pure strategy given  $\pi_n$ , i.e., if the distribution represented by  $F_n(\pi_n, \cdot)$  is supported on some  $y \in \mathbb{R}_+$ , we will identify between  $F_n(\pi_n, \cdot)$  and  $y$  wherever appropriate.

Given a mixed strategy profile  $F = (F_1, \dots, F_N)$ , denote by  $E_n(F)$  the expected payoff of player  $n$  when players use that strategy profile, i.e.,

$$E_n(F) \equiv E\left(\int_0^\infty \dots \int_0^\infty u_n(\cdot, (x_1, \dots, x_N))dF_1(\cdot, x_1), \dots, dF_N(\cdot, x_N)\right).$$

For  $\pi_n \in \Pi_n$ ,  $E_n(F | \pi_n)$  will denote the conditional expected payoff of player  $n$  given his information set  $\pi_n$ , i.e.,

$$E_n(F | \pi_n) \equiv E\left(\int_0^\infty \dots \int_0^\infty u_n(\cdot, (x_1, \dots, x_n))dF_1(\cdot, x_1), \dots, dF_i(\cdot, x_i), \dots, dF_N(\cdot, x_N)\right) | \pi_n.$$

An  $N$ -tuple of mixed strategies  $F^* = (F_1^*, \dots, F_N^*)$  constitutes a Bayesian equilibrium in the common-value all-pay auction  $G$  if for every player  $n$ , and every mixed strategy  $F_n$  of that player, the following inequality holds:

$$E_n(F^*) \geq E_n(F_1^*, \dots, F_n, \dots, F_N^*).$$

### 3 An Example

We begin with a simple example to illustrate the players' behavior in our model. Consider a common-value all-pay auction with two players. Assume that there are three states of nature such that in state  $\omega_i$  the value of winning is  $v(\omega_i) = i$  with probability of  $p_i = \frac{1}{3}$ , for  $i = 1, 2, 3$ . Player 1 knows *only* the prior distribution  $p$ , and hence he has the trivial information partition,  $\Pi_1 = \{\{\omega_1, \omega_2, \omega_3\}\}$ , while player 2 is completely informed of the value of winning, hence  $\Pi_2 = \{\{\omega_1\}, \{\omega_2\}, \{\omega_3\}\}$  partitions  $\Omega$  into singletons.

It can be easily verified that the corresponding common-value all-pay auction does not have an equilibrium in pure strategies. However, there does exist a mixed strategy equilibrium. In this equilibrium, player 1's mixed strategy  $F_1^*$  is a state-independent c.d.f. given by

$$F_1^*(x) = \begin{cases} 0 & \text{if } x < 0, \\ x, & \text{if } 0 \leq x \leq \frac{1}{3}, \\ \frac{x}{2} + \frac{1}{6}, & \text{if } \frac{1}{3} < x \leq 1, \\ \frac{x}{3} + \frac{1}{3} & \text{if } 1 < x \leq 2, \\ 1, & \text{if } 2 < x. \end{cases}$$

Player 2's mixed strategy  $F_2^*$  does depend on the state of nature (of which he is informed):

$$F_2^*(\omega_1, x) = \begin{cases} 0 & \text{if } x < 0, \\ 3x, & \text{if } 0 \leq x \leq \frac{1}{3}, \\ 1 & \text{if } x > \frac{1}{3}, \end{cases}$$

$$F_2^*(\omega_2, x) = \begin{cases} 0, & \text{if } x \leq \frac{1}{3}, \\ \frac{3}{2}x - \frac{1}{2}, & \text{if } \frac{1}{3} < x \leq 1, \\ 1, & \text{if } x > 1, \end{cases}$$

$$F_2^*(\omega_3, x) = \begin{cases} 0, & \text{if } x < 1, \\ x - 1, & \text{if } 1 \leq x \leq 2, \\ 1, & \text{if } x > 2. \end{cases}$$

In order to see that the above strategies are in equilibrium, note that, given player 2's mixed strategy

$F_2^*$ , player 1's expected payoff if he exerts effort  $x \in [1, 2]$  is

$$E_1(x, F_2^*) = \frac{1}{3} \cdot 1 + \frac{1}{3} \cdot 2 + \frac{1}{3} \cdot 3 \cdot (x - 1) - x = 0$$

When  $x \in [\frac{1}{3}, 1]$ ,

$$E_1(x, F_2^*) = \frac{1}{3} \cdot 1 + \frac{1}{3} \cdot 2 \cdot \left(\frac{3}{2}x - \frac{1}{2}\right) - x = 0,$$

and when  $x \in [0, \frac{1}{3}]$ ,

$$E_1(x, F_2^*) = \frac{1}{3} \cdot 1 \cdot (3x) - x = 0.$$

As any effort above 2 would result in a negative expected payoff,  $[1, 2]$  is the set of player 1's pure strategy best responses to  $F_2^*$ , and in particular his mixed strategy  $F_1^*$  is a best response to  $F_2^*$  as it results in an expected payoff of zero.

Now, fix player 1's mixed strategy  $F_1^*$ , and assume that  $\omega_3$  is the realized state of nature. If player 2 exerts effort  $x \in [1, 2]$ , then his conditional expected payoff is

$$E_2(\{\omega_3\}, F_1^*, x) = 3 \cdot \left(\frac{x}{3} + \frac{1}{3}\right) - x = 1.$$

If he exerts  $x \in [\frac{1}{3}, 1]$  or  $x \in [0, \frac{1}{3}]$ , his expected payoff is, correspondingly,

$$E_2(\{\omega_3\}, F_1^*, x) = 3 \cdot \left(\frac{x}{2} + \frac{1}{6}\right) - x = \frac{x}{2} + \frac{1}{2} < 1,$$

or

$$E_2(\{\omega_3\}, F_1^*, x) = 3 \cdot x - x = 2x < 1,$$

and thus, conditional on the realization of  $\omega_3$ ,  $[1, 2]$  is the set of player 2's pure strategy best responses to  $F_1^*$ . In particular, conditional on  $\omega_3$ ,  $F_2^*(\omega_3, \cdot)$  is a mixed strategy best response to  $F_1^*$ .

If  $\omega_2$  is the realized state, by exerting  $x \in [\frac{1}{3}, 1]$  player 2 obtains the expected payoff

$$E_2(\{\omega_2\}, F_1^*, x) = 2 \cdot \left(\frac{x}{2} + \frac{1}{6}\right) - x = \frac{1}{3}.$$

As before, it can be seen that all effort levels outside  $[\frac{1}{3}, 1]$  lead to a lower expected payoff, and thus conditional on  $\omega_2$ ,  $F_2^*(\omega_2, \cdot)$  is a mixed strategy best response to  $F_1^*$ .

If  $\omega_1$  is the realized state, by exerting  $x \in [0, \frac{1}{3}]$  player 2, in expectation, obtains

$$E_2(\{\omega_1\}, x) = 1 \cdot x - x = 0,$$

while effort levels outside  $[0, \frac{1}{3}]$  lead to negative expected payoffs. Thus, also conditional on  $\omega_1$ ,  $F_2^*(\omega_1, \cdot)$  is a mixed strategy best response to  $F_1^*$ . We conclude that  $F_2^*$  is a best response of player 2 also w.r.t. the unconditional expected payoff. Hence, the pair  $(F_1^*, F_2^*)$  is a mixed strategy equilibrium. The expected payoff of player 2 is then

$$E_2(F_1^*, F_2^*) = \frac{1}{3}(E_2(\{\omega_1\}, F_1^*, F_2^*) + E_2(\{\omega_2\}, F_1^*, F_2^*) + E_2(\{\omega_3\}, F_1^*, F_2^*)) = \frac{4}{9}.$$

In the next section, we characterize the players' mixed-strategy equilibrium in a general two-player common-value all-pay auction, and prove its uniqueness.

## 4 Results

### 4.1 Equilibrium analysis

#### 4.1.1 Information advantage assumption

We will consider first the case of two players, deferring the discussion of the general case of  $N \geq 3$  players to Section 4.1.3. Our main assumption will be that player 2 has *information advantage* over player 1, i.e., that the information partition  $\Pi_2$  of player 2 is finer than  $\Pi_1$ . The purpose of this subsection is to observe that, as far as the equilibrium analysis is concerned, the information advantage assumption can be reduced to the postulate that  $\Pi_1 = \{\Omega\}$  and  $\Pi_2 = \{\{\omega_1\}, \{\omega_1\}, \dots, \{\omega_n\}\}$ . That is, it can be assumed w.l.o.g. that player 1 has no information on the realized state of nature (other than the common prior distribution  $p$ ) and thus has the trivial information partition, while player 2 knows the realized state precisely, and thus his information partition is the finest one possible.

Indeed, in the general case of  $\Pi_2$  being finer than  $\Pi_1$  where  $\Pi_1$  is not necessarily the trivial information partition, note the following. Given  $\pi_1 \in \Pi_1$ , the event  $\pi_1$  is common knowledge at any  $\omega \in \pi_1$ . Thus, the equilibrium analysis can be carried out separately for each  $\pi_1 \in \Pi_1$ , as conditional on the occurrence of  $\pi_1$  the common-value all-pay auction  $G$  can be viewed as a distinct common-value all-pay auction  $G'$ ,

where the set of states of nature is  $\Omega' = \pi_1$  and the conditional distribution  $p(\cdot | \pi_1)$  serves as the common prior distribution  $p'$ . In  $G'$ , player 1 has the trivial information partition,  $\Pi_1' = \{\Omega'\}$ . Thus, we may w.l.o.g. assume that  $\Pi_1 = \{\Omega\}$  in the original all-pay auction  $G$ .

Now consider that  $\Pi_2$  is not the finest information partition. Then, consider another common-value all-pay auction  $G''$ , in which the set of states of nature  $\Omega'' \equiv \Pi_2$  consists of information sets of player 2 in  $G$ ; the common value function  $v''$  is given by  $v''(\pi_2) = E(v | \pi_2)$  for every  $\pi_2 \in \Omega''$ ; player 2 has the full information partition, consisting of all singleton subsets of  $\Omega''$ , i.e.,  $\Pi_2'' = \{\{\pi_2\} | \pi_2 \in \Omega''\}$ ; and player 1 has the trivial information partition  $\Pi_1'' = \{\Omega''\}$ . Naturally, every mixed strategy  $F_2(\cdot, \cdot)$  of player 2 in  $G$  corresponds to a unique mixed strategy  $F_2''(\cdot, \cdot)$  of 2 in  $G''$  that is given by  $F_2''(\pi_2, \cdot) = F_2(\omega, \cdot)$  for every  $\pi_2 \in \Omega''$  and every  $\omega \in \pi_2$  (which is well-defined because of  $\Pi_2$ -measurability of  $F_2$  in its first coordinate), and the mixed strategies of player 1 in  $G$  and  $G''$  are identical as they are state-independent. The correspondence  $(F_1, F_2) \leftrightarrow (F_1, F_2'')$  between mixed strategy-profiles in  $G$  and  $G''$  obviously preserves both players' expected payoffs. Thus,  $G$  and  $G''$  are payoff-equivalent, and hence identical in terms of equilibrium analysis. However,  $G''$  has the property that player 1 has no information on the realized state of nature while player 2 is completely informed of it. Thus, in studying equilibria in two-player common-value all-pay auctions, attention can be confined w.l.o.g. to common-value all-pay auctions with the latter property.<sup>6</sup>

#### 4.1.2 Equilibrium analysis in the two-player case

For each state of nature  $\omega_i \in \Omega$ , denote  $v_i = v(\omega_i)$  and  $p_i = p(\omega_i) > 0$ . Assume that the possible values are strictly ranked,  $0 < v_1 < v_2 < \dots < v_n$ , and that (w.l.o.g., as indicated above) player 2 knows the realized value precisely (having the full information partition  $\Pi_2 = \{\{\omega_1\}, \{\omega_1\}, \dots, \{\omega_n\}\}$ ), while player 1 only knows its distribution  $p$  (having the trivial information partition  $\Pi_1 = \{\Omega\}$ ). In what follows, we describe a mixed strategy equilibrium  $(F_1^*, F_2^*)$  of the all-pay auction.

Let  $x_0 \equiv 0$ , and

$$x_i \equiv \sum_{j=1}^i p_j v_j \tag{1}$$

---

<sup>6</sup>See related discussions in Malueg and Orzach (2012) and Forges and Orzach (2011).

for each  $i = 1, \dots, n$ . Thus,  $x_0 < x_1 < \dots < x_n$ . Consider a function  $F_1^*$  on  $\mathbb{R}_+$  given by

$$F_1^*(x) = \begin{cases} 0 & \text{if } x < 0, \\ \cdot & \cdot \\ \frac{x}{v_i} + \sum_{j=1}^{i-1} p_j \left[ 1 - \frac{v_j}{v_i} \right], & \text{if } x \in [x_{i-1}, x_i], \\ \cdot & \cdot \\ 1, & \text{if } x > x_n. \end{cases} \quad i = 1, \dots, n \quad (2)$$

It is easy to see that  $F_1^*(x)$  is well defined, strictly increasing, and continuous. Moreover,  $F_1^*(x_0) = 0$  and  $F_1^*(x_n) = 1$ . Thus,  $F_1^*(x)$  is a c.d.f. of a continuous probability distribution supported on the interval  $[x_0, x_n]$ . (Such a distribution is obtained by assigning probability  $p_i$  to each interval  $[x_{i-1}, x_i]$ , randomly choosing an interval, and then selecting a point w.r.t. the uniform distribution on the chosen interval). Being that the function  $F_1^*$ , is state-independent, it can be viewed as a mixed strategy of the uninformed player 1.

Note next that

$$E_2(\{\omega_i\}, F_1^*, x) = v_i F_1^*(x) - x \quad (3)$$

$$= v_i F_1^*(x_{i-1}) - x_{i-1} = E_2(\{\omega_i\}, F_1^*, x_{i-1}) \quad (4)$$

for every  $x \in [x_{i-1}, x_i]$ , and  $i = 1, \dots, n$ . Thus, given that  $\omega_i$  was realized, the informed player 2 is indifferent between all efforts in the interval  $[x_{i-1}, x_i]$ , provided that his rival acts according to  $F_1^*$ . Since the slopes of the function  $v_i F_1^*(x) - x$  are positive when  $x < x_{i-1}$  and negative when  $x > x_{i-1}$ , the set of player 2's pure strategy best responses is the interval  $[x_{i-1}, x_i]$ .

Now, for each  $i = 1, \dots, n$ , consider a function  $F_2^*(\omega_i, x)$  on  $\mathbb{R}_+$  given by

$$F_2^*(\omega_i, x) = \begin{cases} 0 & \text{if } x < x_{i-1}, \\ \frac{x - \sum_{j=1}^{i-1} p_j v_j}{p_i v_i}, & \text{if } x \in [x_{i-1}, x_i], \\ 1 & \text{if } x > x_i, \end{cases} \quad (5)$$

Note that  $F_2^*(\omega_i, x)$  is well defined, strictly increasing, continuous,  $F_2^*(\omega_i, x_{i-1}) = 0$  and  $F_2^*(\omega_i, x_i) = 1$ . Thus,  $F_2^*(\omega_i, x)$  is a c.d.f. of a probability distribution supported on  $[x_{i-1}, x_i]$ , and in particular  $F_2^*$  constitutes a mixed strategy of player 2. Moreover,

$$E_1(x, F_2^*) = \sum_{j=1}^{i-1} p_j v_j + p_i v_i F_2^*(\omega_i, x) - x = 0 \quad (6)$$

for every  $x \in [x_{i-1}, x_i]$ . Thus, player 1 is (in expectation) indifferent between all efforts in  $[x_0, x_n]$  (and is obviously worse off when efforts are outside  $[x_0, x_n]$ ) provided his rival 2 acts according to  $F_2^*$ .

We conclude that  $(F_1^*, F_2^*)$  is a mixed strategy equilibrium. It turns out that it is the only one:

**Proposition 1** *The mixed strategy equilibrium  $(F_1^*, F_2^*)$  described above is the unique equilibrium in  $G$ .*

**Proof.** See Appendix. ■

#### 4.1.3 The $N$ -player case

We have thus far assumed that there are only two players. It will now be shown that this entails no loss of generality in the following sense. Suppose that there are  $N \geq 3$  players, and that their information endowments can be ranked as follows: player 2 has information advantage over player 1, and player 1 has information advantage over (or the same information endowment as) players 3, ...,  $N$ . Let  $(F_1^*, F_2^*)$  be the unique equilibrium in the contest between 1 and 2 (which exists by Proposition 1 and Section 4.1.1). We claim that in the contest between 1, 2, ...,  $N$ , strategy profile  $(F_1^*, F_2^*, 0, 0, \dots, 0)$  constitutes a Bayesian equilibrium. That is, all but the two players with the best information submit bids of zero which means that they are effectively staying out of contest, while players 1 and 2 behave as if they were engaged in a two-player contest. This will ensure that any  $N$ -player contest in which information endowments are ranked possesses a reduction to the two-player case.

In order to see that  $(F_1^*, F_2^*, 0, 0, \dots, 0)$  is a Bayesian equilibrium, note first that players 1 and 2 have no incentive to unilaterally deviate from their strategies in  $(F_1^*, F_2^*, 0, 0, \dots, 0)$ , since their payoffs are identical to those in a two-player contest where such deviations are not profitable in expectation. Note next that if any of the remaining players (say, player 3) had a profitable deviation  $F_3$  from bid 0, we would have had

$$E_3(F_1^*, F_2^*, F_3, 0, \dots, 0) > E_3(F_1^*, F_2^*, 0, 0, \dots, 0) = 0,$$

and hence

$$E_3(F_1^*, F_2^*, F_3, 0, \dots, 0) > 0.$$

Since player 1 has an information advantage over (or the same information as) player 3,  $F_3$  is also a Bayesian

strategy of player 1. As  $F_1^*$  is 1's best response to  $(F_1^*, F_2^*, 0, 0, \dots, 0)$ , it follows that

$$\begin{aligned} E_1(F_1^*, F_2^*, 0, 0, \dots, 0) &\geq E_1(F_3, F_2^*, 0, 0, \dots, 0) \\ &= E_3(0, F_2^*, F_3, 0, \dots, 0) \\ &\geq E_3(F_1^*, F_2^*, F_3, 0, \dots, 0) > 0. \end{aligned}$$

Thus

$$E_1(F_1^*, F_2^*, 0, 0, \dots, 0) > 0,$$

and in particular  $E_1(F_1^*, F_2^*) > 0$  in the two-player contest between 1 and 2. However, it follows from (6), Proposition 1, and Section 4.1.1 that the expected payoff to player 1 in the unique equilibrium is zero, a contradiction. We conclude that players 3, ...,  $N$  cannot unilaterally deviate from bid 0 and make profit, and hence that  $(F_1^*, F_2^*, 0, 0, \dots, 0)$  is a Bayesian equilibrium of the  $N$ -player contest, as claimed.

In the next section, using the characterization of equilibrium in Proposition 1 in a two-player auction, we study the effect of information on players' payoffs, efforts and probabilities of winning.

## 4.2 Expected payoffs and efforts

We have shown that the equilibrium strategies in a two-payer common-value all-pay auction are determined uniquely. The expected equilibrium payoff of player 1 is zero: it follows from (6) that

$$E_1(F_1^*, F_2^*) = 0. \tag{7}$$

It follows from (3)-(4) that player 2's expected payoff is

$$\begin{aligned} E_2(F_1^*, F_2^*) &= \sum_{i=1}^n p_i (v_i F_1(x_{i-1}) - x_{i-1}) \\ &= \sum_{i=1}^n p_i \left( \sum_{j=1}^{i-1} p_j (v_i - v_j) \right). \end{aligned} \tag{8}$$

The equilibrium strategies  $F_1^*, F_2^*$  of the two players are quite different. Among other distinctions,  $F_2^*$  is state-dependent, while  $F_1^*$  is not. However, both players have the same *ex-ante* distribution of the effort they make. Indeed, for every  $i = 1, 2, \dots, n$ , and every  $x \in [x_{i-1}, x_i]$  (where  $x_i$  is given by (1)), the ex-ante

probability  $F_2(x)$  that player 2 will exert an effort that is smaller than or equal to  $x$  according to his strategy  $F_2^*$  is given by

$$\begin{aligned} F_2(x) &= \sum_{j=1}^{i-1} p_j + p_i F_2^*(\omega_i, x) = \sum_{j=1}^{i-1} p_j + p_i \cdot \frac{x - \sum_{j=1}^{i-1} p_j v_j}{p_i v_i} \\ &= \frac{x}{v_i} + \sum_{j=1}^{i-1} p_j \left[ 1 - \frac{v_j}{v_i} \right] = F_1^*(x). \end{aligned}$$

Thus, the ex-ante distribution of equilibrium effort is identical for both players. This fact leads to the following proposition.

**Proposition 2** *In the unique equilibrium  $(F_1^*, F_2^*)$  of every two-player common-value all-pay auction:*

(i) *each player has probability  $\frac{1}{2}$  to win;*

and

(ii) *both players exert the same expected effort*

$$\sum_{i=1}^n p_i \left( \sum_{j=1}^{i-1} p_j v_j + \frac{1}{2} p_i v_i \right).$$

**Proof.** It was shown above that the players have ex-ante identical (and, obviously, independent) distributions of efforts, and hence, as claimed in (i), each wins the contest with the same probability. It also follows that the expected efforts of both players are equal. Calculating the expected payoff for player 1 (using (2)) leads to the formula claimed in (ii):

$$EE_1 = \int_{x_0}^{x_n} x dF_1^*(x) = \sum_{i=1}^n \int_{x_{i-1}}^{x_i} \frac{x}{v_i} dx = \sum_{i=1}^n \frac{x_i^2 - x_{i-1}^2}{2v_i} = \sum_{i=1}^n p_i \left( \sum_{j=1}^{i-1} p_j v_j + \frac{1}{2} p_i v_i \right).$$

*Q.E.D.* ■

According to Proposition 2, the asymmetry in information does not affect the ratio of the two players' expected efforts, as the expected efforts are equal. However, the asymmetric information does affect the players' expected *total* effort. In the next section we will examine the effect of asymmetry in information on the expected total effort and the expected total payoff.

### 4.3 Comparative results

We just showed that the expected payoff of player 1, over whom player 2 has an information advantage, is zero in equilibrium. We will now examine how the *extent* of information advantage affects the expected

payoff of player 2. Assume, as before, that  $\Pi_1 = \{\Omega\}$  and  $\Pi_2 = \{\{\omega_1\}, \{\omega_1\}, \dots, \{\omega_n\}\}$ . Also consider an additional player 2' with an "intermediate" connected information partition  $\Pi'_2$ , which is a strict coarsening of  $\Pi_2$  and a strict refinement of  $\Pi_1$ . Then we have the following comparative result.

**Proposition 3** *In a two-player common-value all-pay auction, the expected payoff of player 2 (when he competes against player 1) is higher than the expected payoff of player 2' (when he competes against player 1).*

**Proof.** By (8), the expected payoff of player 2, when he competes against player 1, is given in equilibrium by

$$E_2 = \sum_{i=1}^n p_i \left( \sum_{k=1}^{i-1} p_k (v_i - v_k) \right).$$

Regarding player 2', assume first that  $\Pi'_2$  is different from  $\Pi_2$  only in that player 2' cannot distinguish between the states  $\omega_j$  and  $\omega_{j+1}$ , for some  $1 \leq j < n$ . Thus,  $\Pi'_2 = \{\{\omega_1\}, \{\omega_2\}, \dots, \{\omega_{j-1}\}, \{\omega_j, \omega_{j+1}\}, \{\omega_{j+2}\}, \dots, \{\omega_n\}\}$ . The auction in which player 2' competes against player 1 is amenable to our previous analysis, but with a minor modification: the set of states of nature must be redefined as  $\Omega' = (\Omega \setminus \{\omega_j, \omega_{j+1}\}) \cup \{\omega_{j,j+1}\}$ , where the new state  $\omega_{j,j+1}$  is the amalgamation of  $\omega_j$  and  $\omega_{j+1}$ , occurring with probability  $p_{j,j+1} = p_j + p_{j+1}$  and having the common value of  $v_{j,j+1} = \frac{p_j}{p_j + p_{j+1}} v_j + \frac{p_{j+1}}{p_j + p_{j+1}} v_{j+1}$ . In this modified contest (payoff-equivalent to the original), player 1 has the trivial information, while player 2' has the finest possible information partition. Applying (8) to this contest, the expected payoff of player 2 in equilibrium is given by

$$\begin{aligned} E'_2 &= \sum_{i=1}^{j-1} p_i \left( \sum_{k=1}^{i-1} p_j (v_i - v_j) \right) \\ &\quad + p_{j,j+1} \sum_{k=1}^{j-1} p_k (v_{j,j+1} - v_k) \\ &\quad + \sum_{i=j+2}^n p_i \left( \sum_{k \leq i-1, k \neq j, k \neq j+1} p_k (v_i - v_k) + p_{j,j+1} (v_i - v_{j,j+1}) \right). \end{aligned}$$

Then we have

$$E_2 - E'_2 = p_j p_{j+1} (v_{j+1} - v_j) + \sum_{i=j+2}^n p_i \left( \sum_{k=j}^{j+1} p_k (v_i - v_k) - p_{j,j+1} (v_i - v_{j,j+1}) \right).$$

Since  $p_j p_{j+1} (v_{j+1} - v_j) > 0$  and  $\sum_{i=j+2}^n p_i (\sum_{k=j}^{j+1} p_k (v_i - v_k) - p_{j,j+1} (v_i - v_{j,j+1})) = 0$  we obtain that  $E_2 - E'_2 > 0$ .

We have thus shown that player 2' obtains in expectation less than player 2 (when competing against 1 in a two-player auction) if  $\Pi'_2$  is a connected partition which is a strict coarsening of  $\Pi_2$  with  $|\Pi'_2| = |\Pi_2| - 1$ . Inductively, the claim can be extended to *any* connected partition  $\Pi'_2$  with  $|\Pi'_2| < n$ . *Q.E.D.* ■

The next result shows that there is an opposite relation between the players' total expected payoff and their total expected effort (bid).

**Proposition 4** *In a two-player common-value all-pay auction, the expected total effort when player 2 competes against player 1 is lower than the expected total effort when player 2' competes against player 1.*

**Proof.** In every common-value all-pay auction, the relation between the players' expected total effort and their expected total payoff is

$$\text{Expected total effort} = \text{Expected reward} - \text{Expected total payoff}$$

Since the expected payoff of player 1 when he competes against player 2 or against 2' is zero (see (7)), in both auctions

$$\text{Expected total effort} = \text{Expected reward} - \text{Expected payoff of player 2 (or, 2')}$$

By Proposition 3, the expected payoff of player 2 is higher than that of player 2' (when competing against player 1). On the other hand, both contests clearly have the same expected reward,  $E(v)$ . Thus, the expected total effort when player 2 competes against player 1 is lower than when player 2' competes against 1. *Q.E.D.*

■

The above propositions demonstrate that increasing asymmetry between players in a two-player common-value all-pay auction has a positive effect on the expected payoff of the player with an information advantage, and a negative effect on the expected total effort.

## 5 Budget Constraints

We have thus far assumed that players submit any bids they wish without any constraint. In this section we will show that having (even identical) budget constraints can change our results in a significant way. We shall assume, as in Section 4, that there are two players, and that  $\Pi_1 = \{\Omega\}$  and  $\Pi_2 = \{\{\omega_1\}, \{\omega_1\}, \dots, \{\omega_n\}\}$ ,

i.e., player 1 has no information on the realized states of nature (other than the common prior distribution  $p$ ), while player 2 knows the realized state precisely. As before, for each state of nature  $\omega_i \in \Omega$ , denote  $v_i = v(\omega_i)$  and  $p_i = p(\omega_i)$ . Each player can submit any bid that is lower than or equal to a given budget constraint  $d > 0$ . The following example (the same one as in Section 3 but with budget constrained players) demonstrates the effect of the budget constraint on the players' equilibrium strategies, and, in particular, shows that having a budget constraint may imply a higher expected payoff to player 1 (the uninformed player) compared to player 2 (the informed player).

**Example 1** *Assume that  $n = 3$ , and that in state  $\omega_i$  the value of winning is  $v(\omega_i) = i$  with probability of  $p_i = \frac{1}{3}, i = 1, 2, 3$ . Assume also that the players have the same budget constraint,  $d = \frac{5}{6}$ . Then the contest possesses the following pure strategy Bayesian equilibrium: player 1's bid is independent of the state of nature,  $x_1^* \equiv \frac{5}{6}$ , and player 2's state-dependent bid is given by*

$$x_2^*(\omega) = \begin{cases} 0, & \text{if } \omega = \omega_1 \\ \frac{5}{6}, & \text{if } \omega \neq \omega_1 \end{cases}.$$

The expected payoff of player 1 is then

$$E_1 = \frac{1}{3} \cdot 1 + \frac{1}{3} \cdot \frac{1}{2} \cdot 2 + \frac{1}{3} \cdot \frac{1}{2} \cdot 3 - \frac{5}{6} = \frac{1}{3},$$

and the expected payoff of player 2 is

$$E_2 = \frac{1}{3} \cdot \left(\frac{1}{2} \cdot 2 - \frac{5}{6}\right) + \frac{1}{3} \cdot \left(\frac{1}{2} \cdot 3 - \frac{5}{6}\right) = \frac{5}{18}.$$

Thus, the expected payoff of the uninformed player (player 1) is higher than that of the informed player (player 2).

In Example 1, we showed that the uninformed player's expected payoff could be higher than that of the informed player. In the following we describe some sufficient conditions under which this unusual result is obtained.

**Proposition 5** *Consider a two-player common-value all-pay auction with a budget constraint  $d$  for both players. Suppose that there exists  $1 \leq j \leq n - 1$  such that*

(i)

$$\frac{1}{2} \sum_{m=j+1}^n p_m v_m \geq d, \quad (9)$$

(ii)

$$\frac{v_j}{2} \leq d < \frac{v_{j+1}}{2}, \quad (10)$$

and

(iii)

$$\sum_{m=1}^j p_m (v_m - d) \geq 0. \quad (11)$$

Then, there exists a pure strategy Bayesian equilibrium in which the expected payoff of the uninformed player (player 1) is higher than that of the informed player (player 2).

**Proof.** Given the conditions (9) and (10), the contest possesses a pure strategy Bayesian equilibrium  $(x_1^*, x_2^*)$ , in which

$$x_1^* \equiv d, \quad (12)$$

and

$$x_2^*(\omega_k) = \begin{cases} 0, & \text{for } k = 1, \dots, j, \\ d, & \text{for } k = j + 1, \dots, n \end{cases}. \quad (13)$$

If the players use the strategies given by (12) and (13), the expected payoff of player 2 is

$$E_2(x_1^*, x_2^*) = \sum_{m=j+1}^n p_m \left(\frac{1}{2}v_m - d\right), \quad (14)$$

and the expected payoff of player 1 is then

$$E_1(x_1^*, x_2^*) = \sum_{m=1}^j p_m (v_m - d) + \sum_{m=j+1}^n p_m \left(\frac{1}{2}v_m - d\right). \quad (15)$$

To check that  $(x_1^*, x_2^*)$  constitutes an equilibrium, we do the following. If player 1 submits a bid of  $x_1 = \varepsilon < d$ , then by (9)

$$E_1(x_1, x_2^*) = \sum_{m=1}^j p_m v_m - \varepsilon < E_1(x_1^*, x_2^*)$$

Thus  $x_1^*$  is player 1's (unique) best response to  $x_2^*$ .

If player 2 unilaterally deviates from  $x_2^*$  to a strategy  $x_2$  with  $0 < x_2(\omega_k) = \varepsilon \leq d$  for some  $1 \leq k \leq j$ , then

$$\begin{aligned} E_2(\{\omega_k\}, x_1^*, x_2) &\leq \max\left(-\varepsilon, \frac{v_k}{2} - d\right) \\ &\leq 0 = E_2(\{\omega_k\}, x_1^*, x_2^*), \end{aligned}$$

where the second inequality is implied by (10). But, also by (10), if player 2 unilaterally deviates from  $x_2^*$  to a strategy  $x_2$  with  $0 \leq x_2(\omega_k) = \varepsilon < d$  for some  $j+1 \leq k \leq n$ , then

$$\begin{aligned} E_2(\{\omega_k\}, x_1^*, x_2) &= -\varepsilon \\ &\leq 0 \leq \frac{v_k}{2} - d = E_2(\{\omega_k\}, x_1^*, x_2^*), \end{aligned}$$

By taking expectation over  $\omega_k$ , it follows that

$$E_2(x_1^*, x_2) \leq E_2(x_1^*, x_2^*)$$

for *any* pure strategy  $x_2$  of player 2 that obeys his budget constraint, and thus  $x_2^*$  is player 2's best response to  $x_1^*$ .

We can conclude now that  $(x_1^*, x_2^*)$  is an equilibrium. By comparing the players' expected payoffs given by (14) and (15), we obtain that the expected payoff of player 1 is higher than that of player 2 if and only if (11) holds. Q.E.D. ■

The existence of a pure strategy equilibrium as established in Proposition 5 is based on assumptions (9) and (10). Furthermore, if the budget constraint  $d$  is below  $\frac{v_1}{2}$ , both players would make a bid equal to the bid cap in all the states of nature in a pure strategy equilibrium. But our model with identical budget constraints may also have a mixed strategy equilibrium, and for a sufficiently large cap  $d$  the equilibrium would in fact be unique and identical to the one in Proposition 1.

## 6 Concluding remarks

In models with asymmetric information, differences in players' information usually result in different equilibrium strategies, probabilities of winning, and expected payoffs. In this model we show that even when the

players' information can be ranked, with one player having an information advantage over his opponent, the players' expected efforts as well as their probabilities of winning the contest are the same. The difference in information only manifested itself in the different expected payoffs. We also show that the highest expected total effort is obtained when the difference in the players' information is as small as possible. Thus, a contest designer who wishes to maximize the players' expected total effort has an incentive to reduce the information difference between the players. But, if players face budget constraints, the information advantage might become a disadvantage: the player with the information advantage may have a lower expected payoff than his opponent. This unusual result implies that by imposing bid caps, the contest designer can control the relation between the players' expected payoffs.

We established our results under the assumptions that information sets of each player are connected with respect to the value of winning the contest and that the different information endowments can be ranked. These assumptions are found to be sufficient for the existence of a unique equilibrium. When information cannot be ranked, however, the existence of an equilibrium remains an open problem.

It would be interesting to examine whether the results in this paper can, at least partially, carry over to other contest forms with common values and asymmetric information. In particular, the question of how asymmetric information is reflected in the relation between the players' expected efforts and in their probabilities of winning seems worthy of further attention.

## 6.1 Proof of Proposition 1

Fix an equilibrium  $(F_1, F_2)$  in the auction  $G$ . We will prove that  $(F_1, F_2) = (F_1^*, F_2^*)$ .

In what follows, for  $k = 1, 2$  and  $\omega \in \Omega$ ,  $F_k(\omega, \cdot)$  will be treated either as a *probability distribution* on  $\mathbb{R}_+$ , or as the corresponding *c.d.f.*, depending on the context. Also, as  $F_1$  is state-independent,  $F_1(\omega, \cdot)$  will be shortened to  $F_1(\cdot)$ , whenever convenient.

Notice that  $F_k(\cdot, \{c\}) \equiv 0$  for any effort  $c > 0$  and  $k = 1, 2$ . Indeed, if  $F_k(\omega, \{c\}) > 0$  for some  $k$  and  $\omega$ , then  $F_m(\omega', (c - \varepsilon, c]) = 0$  for the other player  $m$  and every  $\omega' \in \Omega$ , and some sufficiently small  $\varepsilon > 0$ . But then  $k$  would be strictly better off by shifting the probability from  $c$  to  $c - \frac{\varepsilon}{2}$ , a contradiction to  $F_k$  being an equilibrium strategy. Thus,  $F_1(\cdot), F_2(\omega, \cdot)$  are non-atomic on  $(0, \infty)$  for every  $\omega \in \Omega$ . Notice also that there

is no interval  $(a, b) \subset (0, \infty)$  on which in some state of nature *only one* player places positive probability according to his equilibrium strategy. Indeed, otherwise there would exist  $a' > a$  such that only one player places positive probability on  $(a', b)$ , and it would then be profitable for that player to deviate (in at least one state of nature, if this is the informed player 2) by shifting positive probability from  $(a', b)$  to  $a'$ .

Suppose now that there is a bounded interval  $(a, b) \subset (0, \infty)$  such that  $F_1((a, b)) = 0$  (and thus  $F_2(\omega, (a, b)) = 0$  for every  $\omega \in \Omega$ , by the previous paragraph), but  $F_1([0, a]) > 0$  and  $F_1([b, \infty)) > 0$ . By extending this interval if necessary, it can also be assumed that  $(a, b)$  is maximal with respect to this property, i.e., that  $F_1([\max(a - \varepsilon, 0), a]) > 0$  and  $F_1([b, b + \varepsilon]) > 0$  for every small enough  $\varepsilon > 0$ . However, using the fact that  $F_2(\omega, \cdot)$  is non-atomic on  $(0, \infty)$  for every  $\omega \in \Omega$ , the expected payoff of player 1 at  $\frac{a+b}{2}$  is strictly bigger than his payoff for any effort in  $[b, b + \varepsilon]$ , if  $\varepsilon > 0$  is small enough. This contradicts the assumption that  $F_1([b, b + \varepsilon]) > 0$ . This contradiction shows that there exists no interval  $(a, b)$  as above, meaning that  $F_1(\cdot)$  must have *full support* on some closed interval. Denote this interval<sup>7</sup> by  $[c, d]$ . Notice also that, for every  $\omega \in \Omega$ ,  $F_2(\omega, \cdot)$  must be supported on the interval  $[c, d]$  (though there need not be full support), since otherwise there would be an interval where only player 2 places positive probability, and this was ruled out.

Note next that  $c = 0$ . Indeed, if  $c > 0$  then  $F_2(\cdot, \{c\}) \equiv 0$ , and thus player 1 has a negative expected payoff for efforts in  $[c, c + \varepsilon]$  for all small enough  $\varepsilon > 0$  (because with efforts in  $[c, c + \varepsilon]$  he loses the contest almost for sure while expending positive effort of at least  $c$ ). He would then profitably deviate from  $F_1$  by shifting the probability from  $[c, c + \varepsilon]$  to effort 0. Thus, indeed,  $c = 0$ . Note also that the interval  $[0, d]$  is non-degenerate, i.e.,  $0 < d$ , since otherwise the equilibrium strategies would prescribe the constant effort 0, and it is clear that each player would have a profitable unilateral deviation to some  $\varepsilon > 0$ .

Given  $i$ ,  $i = 1, \dots, n$ , we will now show that  $F_2(\omega_i, \cdot)$  has full support on a (possibly degenerate) *subinterval* of  $[0, d]$ . Indeed, if not, there would exist an open subinterval  $(a, b) \subset [0, d]$  such that  $F_2(\omega_i, (a, b)) = 0$ , but  $F_2(\omega_i, [0, a]) > 0$  and  $F_2(\omega_i, [b, d]) > 0$ . Since  $F_1((a, b)) > 0$ , there must be  $j \neq i$  such that  $F_2(\omega_j, (a, b)) = 0 > 0$ . Assume that  $i < j$  (the opposite case is treated similarly). Then there are  $x \in [b, d]$  and  $y \in (a, b)$

<sup>7</sup>The interval must be bounded as no efforts above  $v_n$  will be made in equilibrium, due to the associated negative payoff.

such that

$$v_i F^1(x) - x = E_2(\{\omega_i\}, F^1, x) \quad (16)$$

$$\geq E_2(\{\omega_i\}, F^1, y) = v_i F^1(y) - y \quad (17)$$

and

$$v_j F^1(x) - x = E_2(\{\omega_j\}, F^1, x) \quad (18)$$

$$\leq E_2(\{\omega_j\}, F^1, y) = v_j F^1(y) - y. \quad (19)$$

But  $x > y$ , and therefore

$$(v_j - v_i)F^1(x) > (v_j - v_i)F^1(y) \quad (20)$$

since  $v_i < v_j$  and the c.d.f.  $F^1$  is strictly increasing on  $[0, d]$ . Adding (20) to the inequality in (16)-(17) contradicts the inequality obtained in (18)-(19), and therefore no such  $(a, b)$  exists. Consequently, each  $F_2(\omega_i, \cdot)$  has full support on some subinterval<sup>8</sup>  $[a_i, b_i]$  of  $[0, d]$ . Moreover, if  $i < j$  then  $[a_i, b_i]$  lies below  $[a_j, b_j]$  (barring boundary points), since otherwise it would have been possible to find  $x > y$ , where  $x \in [a_i, b_i]$  and  $y \in [a_j, b_j]$ , such that inequalities (16)-(17) and (18)-(19) hold. As above, this would lead to a contradiction via (20).

Thus, the intervals  $\{[a_i, b_i]\}_{i=1}^n$  are disjoint (barring boundary points), and "ordered" according to the index  $i$  on the interval  $[0, d]$ . Moreover,  $\cup_{i=1}^n [a_i, b_i] = [0, d]$ , since otherwise there would be a "gap"  $(a, b)$  on which only player 1 places positive probability, which is impossible as we have seen earlier. It follows that there are points  $0 = x_0 \leq x_1 \leq \dots \leq x_n \equiv d$  such that  $[a_i, b_i] = [x_{i-1}, x_i]$  for every  $i = 1, 2, \dots, n$ , i.e.,  $F^1(\cdot)$  has full support on  $[0, x_n]$ , and, for  $i = 1, \dots, n$ ,  $F_2(\omega_i, \cdot)$  has full support on  $[x_{i-1}, x_i]$ . Denote by  $i_0$  the smallest integer with  $x_{i_0} > 0$ .<sup>9</sup>

Since  $F^1(\cdot)$  has full support on  $[0, x_n]$  and  $F_2(\omega, \cdot)$  has no atoms (except possibly at 0), player 1 is indifferent between any two efforts in  $(0, x_n]$ . Thus, the following equality must hold for every  $i = i_0, \dots, n$  and every positive  $x \in [x_{i-1}, x_i]$ :

$$\sum_{j=1}^{i-1} p_j v_j + p_i v_i F_2(\omega_i, x) - x = E_1(x, F_2) = \lim_{y \searrow 0} E_1(y, F_2) \equiv e_1 \geq 0.$$

<sup>8</sup>All these subintervals are either non-degenerate (of positive length), or  $\{0\}$ , as only the latter can be an atom of  $F_2(\omega_i, \cdot)$ .

<sup>9</sup>Since each interval  $[x_{i-1}, x_i]$  is either non-degenerate or  $\{0\}$ ,  $0 = x_0 = \dots = x_{i_0-1} < x_{i_0} < \dots < x_n$ .

In particular,

$$F_2(\omega_i, x) = \frac{x - \sum_{j=1}^{i-1} p_j v_j + e_1}{p_i v_i} \quad (21)$$

for every  $i = i_0, \dots, n$  and every positive  $x \in [x_{i-1}, x_i]$ . Since  $F_2(\omega_i, \cdot)$  is supported on  $[x_{i-1}, x_i]$ , we have

$F_2(\omega_i, x_i) = 1$ , and thus

$$x_i = \sum_{j=1}^i p_j v_j - e_1 \quad (22)$$

for every  $i = i_0, \dots, n$ .

Since, for  $i = i_0, \dots, n$ ,  $F_2(\omega_i, \cdot)$  has full support on  $[x_{i-1}, x_i]$  and  $F_1(\cdot)$  has no atoms (except, possibly, at 0), player 2 is indifferent between all positive efforts in  $[x_{i-1}, x_i]$ . Thus, the following equality must hold for every positive  $x \in [x_{i-1}, x_i]$ :

$$\begin{aligned} v_i F_1(x) - x &= E_2(\{\omega_i\}, F_1, x) \\ &= E_2(\{\omega_i\}, F_1, x_i) = v_i F_1(x_i) - x_i. \end{aligned}$$

In particular,

$$F_1(x) = \frac{x}{v_i} + F_1(x_i) - \frac{x_i}{v_i},$$

and using the fact that  $F_1(x_n) = 1$  and (22), we obtain

$$F_1(x) = \frac{x + e_1}{v_i} + \sum_{j=1}^{i-1} p_j \left[ 1 - \frac{v_j}{v_i} \right] \quad (23)$$

for every  $i = i_0, \dots, n$ , and every positive  $x \in [x_{i-1}, x_i]$ .

If  $e_1 > 0$ , it follows from (23) that  $F_1(\cdot)$  has an atom at effort 0. Then, obviously  $F_2(\omega_i, \cdot)$  cannot have an atom at 0, for any  $i$ , since otherwise each player would have a profitable unilateral deviation that shifts the probability from zero to an effort slightly above zero. In particular, all intervals  $\{[x_{i-1}, x_i]\}_{i=1}^n$  are non-degenerate, i.e.,  $i_0 = 1$ . But then, by (21),  $F_2(\omega_1, \cdot)$  has an atom at 0, a contradiction. We conclude that  $e_1 = 0$ .

If  $i_0 > 1$ ,  $x_{i_0-1} = 0$ , and thus (21) should hold for  $i = i_0$  and any sufficiently small  $x$ . But then, if  $x < p_1 v_1$

$$F_2(\omega_{i_0}, x) = \frac{x - \sum_{j=1}^{i_0-1} p_j v_j}{p_{i_0} v_{i_0}} \leq \frac{x - p_1 v_1}{p_{i_0} v_{i_0}} < 0,$$

and thus  $F_2(\omega_{i_0}, x)$  is not a c.d.f., a contradiction. Consequently,  $i_0 = 1$ .

It now follows from (22), (21), and (23) that

$$x_i = \sum_{j=1}^i p_j v_j$$

for every  $i = 1, \dots, n$ , that

$$F_1(x) = \frac{x}{v_i} + \sum_{j=1}^{i-1} p_j \left[ 1 - \frac{v_j}{v_i} \right]$$

for every  $i = 1, \dots, n$  and every  $x \in [x_{i-1}, x_i]$ , and that

$$F_2(\omega_i, x) = \frac{x - \sum_{j=1}^{i-1} p_j v_j}{p_i v_i}$$

for every  $i = 1, \dots, n$  and positive  $x \in [x_{i-1}, x_i]$ . Thus,  $(F_1, F_2)$  coincides with  $(F_1^*, F_2^*)$  as described in (2)

and (5).

Q.E.D.
